## Data structures - Advanced R.

A data frame is a very important data type in R. It's pretty much the de facto data structure for most tabular data and what we use for statistics. Data frames can have additional attributes such as `rownames()`, which can be useful for annotating data, like `subject_id` or `sample_id`.

Functional Programming in R Book Description: Master functions and discover how to write functional programs in R. In this concise book, you ' ll make your functions pure by avoiding side-effects; you ' ll write functions that manipulate other functions, and you ' ll construct complex functions using simpler functions as building blocks.

A data frame is the most common way of storing data in R, and if used systematically makes data analysis easier. Under the hood, a data frame is a list of equal-length vectors. This makes it a 2-dimensional structure, so it shares properties of both the matrix and the list.

## R Data Structures and Algorithms - Packt

R is an object-oriented language and all data structures are objects. R doesn't provide programmers direct access to memory and all data must be accessed via symbols or variables that refer to objects. Since vectorized operation is an important aspect of R, R does not have any scalars.

Purely functional data structure. The main difference between an arbitrary data structure and a purely functional one is that the latter is (strongly) immutable. This restriction ensures the data structure possesses the advantages of immutable objects: (full) persistency, quick copy of objects, and thread safety.

Data Types (Structures) in R. Unlike SAS and SPSS, R has several different data types (structures) including vectors, factors, data frames, matrices, arrays, and lists. The data frame is most like a dataset in SAS. A vector is an object that contains a set of values called its elements. The operator `<-` is equivalent to "=" sign.

Functional Data Structures in R: Advanced Statistical ...

Functional data structures are special forms of data structure, which are implemented primarily in functional programming languages. R supports functional programming by providing tools for creation and manipulation of functions. For example, R support assigning functions to variables and passing them as an argument within a function. The R support generating the function dynamically and returning them as a result of the function is also known as a closure function.

Vector is one of the basic data structures in R programming. It is homogenous in nature, which means that it only contains elements of the same data type. Data types can be numeric, integer, character, complex or logical. The vector in R programming is created using the `c()` function.
