Membrane Distillation « Deltapore

Membrane Distillation (MD) is a thermally-driven separation process, in which only vapour molecules transfer through a microporous hydrophobic membrane. The driving force in the MD process is the vapour pressure difference induced by the temperature difference across the hydrophobic membrane.

Membrane distillation is a membrane separation process which may overcome some limitations of other membrane technologies. In particular, high solute concentrations can be reached, overcoming concentration polarization phenomena and ultrapure water can be produced as a permeate.

The membrane distillation (MD) is a relative new and promising technology for brackish and seawater desalination. It is a technology of small to medium desalinated water supplies, operating at atmospheric pressure and temperatures below 100°C and therefore is suitable for solar energy supply.

Membranes used for membrane distillation (MD) inhibit passage of liquid water while allowing permeability for free water molecules and thus, for water vapour.

These membranes are made of hydrophobic synthetic material (e.g. PTFE, PVDF or PP) and offer pores with a standard diameter between 0.1 and 0.5 μm .

INTRODUCTION TO DESALINATION TECHNOLOGIES

Membrane distillation is an emerging non-isothermal membrane process which uses thermal energy in order to provide a vapor phase of volatile molecules present in the feed stream (i.e. mostly water) and condensing of the permeated vapor in the cold side (Figure 2). The driving force in MD is the

Membrane distillation. Water vapour is transported through the membrane due to a pressure difference caused by the difference in temperature. Because the MD module houses a range of evaporation stages as part of an almost ideal counter-current flow process, a very high recovery of evaporation heat is possible.
